Abstract: The physico-chemical parameters and plankton diversity of Awba Reservoir, University of Ibadan was sampled from April to July, 2011. Surface water samples were collected for physico-chemical parameters. Values of the physico-chemical parameters observed ranged as follows: water temperature, 24-26.5°C; air temperature, 22-23.6°C; transparency, 0.2-0.4 m; pH, 7.3-8.4; total dissolved solids, 143.8-159.5 mg/L; conductivity, 290.8-391.5 µmhos/cm; salinity, 0.11-0.19%; dissolved oxygen, 0.7-1.8 mg/L and alkalinity, 0.8-1.7 mg CaCO3/L. Thirty six taxa of plankton were encountered. Phytoplankton consisted of five families namely; Cyanophyceae, Chlorophyceae, Euglenophyceae, Bacillariophyceae and Dinophyceae. Three groups of zooplankton encountered were copepods, cladocerans and rotifers. The presence of pollution indicator species such as, Microcystis, Phacus, Oscillatoria, Surirella Closterium, Aphanocapsa, Anabaena and Euglena show that the Reservoir is likely polluted.

Keywords: Physico-chemical parameters, plankton, pollution and Awba reservoir

INTRODUCTION

Reservoirs are very large natural or artificial lakes that provide habitat and food for many species of fish and wildlife (Dinar et al., 1995). They are constructed for domestic use where large natural lakes are sparse and unsuitable for human exploitation, enhancement of fisheries and improvement of water transport. Freshwater ecosystems have been used for the investigation of factors controlling the abundance and distribution of aquatic organisms (Atobatele and Ugwumba, 2008; Esenowo and Ugwumba, 2010). Changes in the physico-chemical parameters may positively or negatively affect the biota of water bodies in a number of ways such as their survival and growth rate and these may eventually result in disappearance of some species of organisms or its reproduction (Edward and Ugwumba, 2010). Light penetration, temperature, water current and salinity affect the distribution of plankton and other organism (Spodniewska, 1974).

Planktonic communities are influenced by the prevailing physico-chemical parameters and these determine their abundance, occurrence and seasonal variations (Rothhaupt, 2000). Plankters respond quickly to environmental changes because of their short life cycle, hence, their species composition are more likely to indicate the quality of the water which they are found. The relative abundance of chlorophyll is indicative of productive water (Jenkinson and Hickman, 2007). Diatomic species such as Nitschia, Gyrosigma and Epithemia are known to avoid acid water and very low concentration of calcium and magnesium (Mason, 1990). Dense surface blooms of blue-green algae are regarded as indicator of potential productivity in fish pond, while increase of Cyclotella species is an indicator of acidification (Mason, 1991).

Awba Reservoir, University of Ibadan is a man-made lake that serves as a source of water supply to the water treatment plant for domestic uses in the University. The Awba Stream serves as a sink for the disposal of untreated effluents from the student residential halls, Zoological Garden, Faculty of Science laboratories and its environment. Knowledge of physico-chemical parameters and plankton of any body of water is not only useful in assessing its productivity, but would also allow for a better understanding of its biota. Several studies have been carried out in Awba Reservoir, Ita (1993) earlier studied the food and feeding relationship of the fishes in the lake and the feeding cycle of Tilapia zilli, while Ugwumba and Ugwumba (1993) also studied the physico-chemical hydrology and plankton of Awba Reservoir. Physico-chemical parameters and biota of any water body is known to change overtime and so the need to know the prevailing conditions the physi-chemical parameter and plankton abundance of the Awba Reservoir.

MATERIALS AND METHODS

Study area: Awba Reservoir lies between latitude 7°26'-7°27'N and longitude 3°53'-3°54' E, south
western of the University of Ibadan (Fig. 1). The reservoir was constructed in 1964 and expanded to its present size in 1971 by damming the Awba Stream at a point where it flowed through a natural valley. The dam is about 8.5 m high, 110 m long with a crest of about 12.2 m. The reservoir has a maximum length of about 700 m and a maximum depth of 5.5 m with a surface area of about 6 ha (Ugwumba and Ugwumba, 1993). Throughout the year, the water remains relatively constant, while excess water is made to spill away.

Three sampling stations were chosen for the study in the reservoir. Station 1 was located at the entrance point to the reservoir facing Macaulay Road and behind Faculty of Science Lecture Theatre. Station 2 was located at the back of Imo Street adjacent to the reservoir and close to Faculty of Technology. Station 3 is positioned near the dam wall.

**Determination of physico-chemical parameters:**
Surface water samples were collected monthly from April-July, 2011. The physico-chemical parameters determined were pH, conductivity, total dissolved solids, dissolved oxygen, alkalinity and salinity. Temperature and transparency were measured in situ. Air and surface water temperature was determined using a centigrade mercury-in-glass thermometer of range 10-110°C and the results were expressed in degrees Celsius (°C). The hydrogen ion concentration (pH) was determined in the laboratory using Buffered electronic pH meter. Salinity, TDS and conductivity were measured using an Extech meter Model ExStik EC400. Transparency was measured using a secchi disc. Dissolved oxygen concentration was determined using the azide modification of the iodometric method as reported by Greenberg *et al.* (1998). Alkalinity was measured with LaMotte Freshwater Aquaculture Test Kit Model AQ-2. The results were expressed as mg/L.

Plankton samples were collected with a plankton net (55 µm) mesh size, just below the surface water. Samples collected in 250 mL bottles were immediately fixed and preserved in 4% formalin solution in the field according to Onyema (2007). The preserved plankton samples was allowed to settle first and 5 mL of the sample was withdrawn and placed in Sedge-wick rafter counting chamber using a pipette and observed under the microscope. Keys provided by Prescott (1954), Whitford and Schumacher (1973), Needham and Needham (1962), Jeje and Fernando (1986, 1991), Maosen (1978), APHA/AWWA/WEF (1998) and Nwankwo (2004) were used for identification of the plankton species. The total number of organisms per millilitre for each sample was determined by simple calculation after counting the number in the 5 mL sub-sample examined. Cells of phytoplankton were counted. Biological data for plankton was analyzed using quantitative indices to determine the relative abundance and diversity of species and groups using PAST software.

**RESULTS**

The physico-chemical parameters of Awba reservoir: Table 1 shows the mean, standard error and range of physico-chemical parameters of Awba Reservoir measured during the study period. Figure 2 to 8 shows the monthly variation of the measured physico-chemical parameters for the study period. The lowest
mean air and water temperatures were recorded in June while the highest mean temperature was in April. Transparency was highest in April and lowest in July.

Phytoplankton composition and abundance: Five groups of phytoplankton namely Cyanophyceae, Bacillariophyceae, Chlorophyceae, Dinophyceae and Euglenophyceae were encountered in the reservoir. The most abundant phytoplankton was the blue-green algae, Microcystis with a relative abundance of 47% and the least was the dinoflagellate Peridinium with a relative abundance of 1.17% (Table 3). Four colonial forms of Cyanophyceae; Microcystis, Aphanocapsa, Oocystis and Chrocococcus and two filamentous forms; Anabaena, Oscillatoria were encountered.

Zooplankton composition and abundance: The zooplankton encountered were Rotifer, Crustacea and gastropod eggs. Rotifers included Ascomorpha and Platynias while Crustaceans were Cladocera and Copepoda. The cladocerans included Moina while copepods comprised of Thermocyclops, Mesocyclops and nauplius larvae. The most abundant zooplankton was the copepod Thermocyclops with a relative abundance of 95.34% and the least abundant was the cladoceran, Moina with 22.16% relative abundance (Table 4).
DISCUSSION

Physico-chemical parameters: The physico-chemical parameters of Awba Reservoir show variation. These variations may be associated with patterns of water use and rainfall (Ayoade et al., 2006). Temperatures were relatively lower in June-July than in April-May. Water temperature values followed closely changes in air temperature. This may be attributed to the sampling time which was between 8:00 and 10:00 am, when the water is warmer than air. The relationship between surface water temperature and transparency were significant positively. This could be possible because light heats the surface of the water before penetrating into other depths. Temperature is an important factor that influences primary production in reservoir (Lewis, 2000). The dissolved oxygen value for the reservoir was very low. This depression in dissolved oxygen level could be due to chemical and biological oxidation process in water. Sources of dissolved oxygen in the aquatic environment include the atmosphere and photosynthesis. This depends on its solubility while a loss of oxygen includes respiration, decay by aerobic bacteria and decomposition of dead decaying sediments (Gupta and Gupta, 2006).

The pH range shows that the reservoir is tending towards alkalinity. Idowu and Ugwumba (2005) recorded pH values ranging from 6.9-9.6, while Ayoade et al. (2006) reported a pH range of 6.2-8.5 in Awba Reservoir. This suggests that the reservoir water is good for fish production. Accumulation of free carbon dioxide due to little photosynthetic activities of phytoplankton will lower the pH value of the water while intense photosynthetic activities of the phytoplankton will reduce the free carbon dioxide content resulting in increased pH values (Egborge, 1981; Gupta and Gupta, 2006).

The values of salinity recorded throughout the study period were constant. Salinity was very low and show no relationship with other physico-chemical parameters since the reservoir is fresh water and the salt content of a fresh water body is usually low. The fluctuations in total alkalinity of tropical water bodies depend on the location, season, plankton population and nature of the bottom deposits. The values of alkalinity obtained were very low.

The mean value of conductivity (347.44±36.96 μmhos/cm) shows that the conductivity level is intermediate. Conductivity levels below 50 μmhos/cm are considered to be low; those between 50-600 μmhos/cm are medium while those above 600 μmhos/cm are high conductivity (Adeleke, 1982). Akin-Oriola (2003) opined that the conductivity of Awba Reservoir could be regarded as intermediate (239.65±74.31 μmhos/cm).

The Total Dissolved Solid (TDS) values obtained during the study periods were relatively constant all through the stations. This may be due to organic and inorganic substances dissolved and washed into the reservoir by runoffs. The correlation between TDS and air temperature suggests that the dissolved solids in the dam are mainly ionic.

The decrease in transparency from April to July may be due to the increase in turbidity of the water as a result of run-off carried into the reservoir. This agrees with Olaniyi (1969) who reported that the pattern of change of transparency varies inversely with that of turbidity and rainfall and that higher transparency leads to deeper light penetration and consequently a wider depth of photosynthetic activity of phytoplankton.

Plankton composition: The most abundant phytoplankton group in the reservoir during the study period was the Cyanophyceae (blue-green algae). This agrees with the observations of Ugwumba and Ugwumba (1993) that blue-green algae dominated the reservoir. Blue-green algae, mainly Microcystis dominated the phytoplankton in Awba Reservoir. Microcystis have been reported to dominate the phytoplankton group in Lake George, Uganda (Burgis et al., 1973) and Lake Asejire, Nigeria (Egborge, 1979) while Anabaena, a filamentous form of blue-green algae was reported to dominate phytoplankton in Lake Rudolf, Kenya and diatoms in Lake Albert (Fish, 1955). The occurrence of Microcystis, Anabaena and Aphanocapsa is a clear indication that Awba reservoir is polluted. This could be as a result of anthropogenic activities, such as chemicals and wastes washed into it from Chemistry and Zoology Departments, washing of clothes and bathing done sometimes around the dam. Cole (1978) reported that in lakes where domestic, agricultural and industrial pollution is accelerated, growth of blue-green algae results in noxious water bloom of such form as Microcystis and Anabaena. A similar observation was made by Egborge (1972) that Anabaena and Microcystis are indication of Eutrophication following upwelling in Lake Kainji, Nigeria. The presence of Oscillatoria indicates the presence of high concentrations of organic matter and low oxygen content. Rao (1955) reported that Oscillatoria are favored by the high concentration of organic matter and low oxygen content.

Crustaceans, mainly copepods dominated the zooplankton community of the reservoir. This was followed by rotifers. Egborge (1981) reported that there was alternation in abundance between crustaceans and rotifers in Lake Asejire resulting in abundance of all zooplankton year round in the Lake. In the present study, copepods were the most abundant throughout the study period. The Cladocerans were represented by Moina sp.

The physico-chemical characteristics of the Awba Reservoir varied from station to station. The variations observed showed the effects of these parameters on the water quality and plankton abundance. The presence of pollution indicator phyto and zooplankton species shows that the reservoir is under pollution stress. Immediate action needs to be taken to reduce the
increasing levels of anthropogenic activities which have resulted in the pollution of the reservoir thereby reducing the water quality and making the reservoir water unfit for human consumption.
